

Why AI won't replace me

By Ethan Kennedy

ENG 1103, 12/10

As AI continues to develop and become more advanced, many believe it will eventually take over most human coding jobs and therefore make programmers less needed. Some argue that AI can already do everything better than a human because it can generate code and work much more efficiently than we can. They also argue that it's cheaper and more accurate than humans, which would make it more attractive to companies or corporations. Along with those issues with companies, they assume that with these advancements, human creativity and judgment will become obsolete against a simply all-around better alternative. This means that people like me, who have creativity and thoughtful skills and that are able to compete with AI, won't be able to because we're obsolete. Because AI only needs data and prompts to problem-solve, it would make sense that it replaces all parts of coding. These points ignore the actual reality of how necessary humans are to the process. Coding depends on human creativity, judgment, guidance, and deep thinking, which are skills that I rely on every day. Although AI is becoming cheaper, faster, and more accurate at basic coding tasks, it will not fully replace my job since people need creativity and deep thinking that AI cannot replace.

AI can only do basic and repetitive coding tasks, but I can use my creativity to solve problems that AI cannot. AI can really only follow already existing patterns and cannot think of new or original solutions. "While AI demonstrates remarkable proficiency in automating routine statistical tasks such as data cleaning, basic modelling, and code generation."(Mohammed,2025) Since generative AI can only repeat what it's already learned

and can't create new ideas by itself without input. This in turn shows that it stops where creative or original thinking is needed, but I don't. My creativity allows me to come up with designs, ideas, and approaches to take that AI isn't made to do. "Human engineers can devote themselves to architecture, design, and the genuinely novel problems still beyond a machine's reach."(MIT, 2025) Human creativity still has an advantage over AI in building software and or coding. I can think beyond patterns which allows me to create ideas that AI cannot come up with. This helps when a project needs something outside the box. Because coding often requires new solutions and not repeats of the same problems, therefore I stand out since my creativity keeps me valuable in a way that cannot be replaced. Since many coding challenges are often unpredictable, they require original and creative solutions that AI cannot do itself. (MIT,2025) Creative thinking will always be needed in some way for the unpredictable parts, because AI can only assist with broad, repetitive, or quick tasks. Since AI can only do these sorts of tasks, I can solve issues that it cannot see or do. This makes my creative and thinking skills an important factor.

My deep thinking allows me to understand and work on complex coding problems that AI cannot fully understand or do. Complex coding issues need methodical reasoning, context, and understanding of code or real-world issues, which are all skills that I have that AI doesn't. "Long-horizon code planning requires a sophisticated degree of reasoning and human interaction."(IBM, 2024) Because humans can understand the consequences and impact of the decisions that are made, AI will not be able to fully process these scenarios in the same way. My critical thinking about the code allows me to break difficult problems down and make decisions on the best course of action. AI cannot understand the trade-offs/risks of memory and performance or it can't choose the best course of action since it can only follow instead of creating or making decisions. (IBM,2024, and MIT,2025) This shows that human judgment is still needed to balance solutions and to avoid massive failures. I can understand the risks and

tradeoffs so when something complicated happens, I can think deeper and make a smarter, more logical choice than AI. This is important because a lot of different coding problems require careful judgement not a simple pass over guess. Complex coding problems and many other tasks still are going to rely on human judgment, so programmers who have skill sets like these are still necessary. "While AI excels at generating the routine 70% of code, the critical 30% encompassing architecture, security, performance optimization and business logic remains uniquely human territory."(McCarthy,2025) The 30 percent mentioned includes the most important decisions that are made, which shows that humans still have a huge say and impact on projects.

Even if AI is faster and cheaper, it still needs my oversight to help guide and improve it so that it matches the project's goals. AI can't fully learn/understand the meaning or purpose of what a project is supposed to actually do. "AI struggles with "sweeping scopes involving huge codebases, the extended context lengths of millions of lines of code, higher levels of logical complexity, and long-horizon or long-term planning."(UNU,2025) Humans are needed to guide and explain the purpose to AI since it cannot do it on its own. Even if those facts are true, I still need to review the code and correct mistakes so that it meets the real-world needs.

AI-generated code can often contain errors, security problems, or assume incorrect actions, which must be corrected manually by a human before it can be used. (McCarthy,2025) Since AI can contain errors, companies and corporations still need human review to make sure the code is trustworthy. Without human oversight, AI might write code too fast that doesn't work, isn't understandable, or also creates problems later on. "25% of developers estimate that 1 in 5 AI-generated suggestions contain factual errors or misleading code."(Qodo,2025) This means

that faulty code can create expensive and time-consuming mistakes that can cause failure or security problems. Since I can pay closer attention to specific parts of code, I can catch errors before anything bad happens. This will prevent issues early on and it ensures that projects will run smoothly.

I can handle the unexpected parts of coding since my skills and judgement will help me know how to fix broken AI. Because AI can break when something goes wrong, it cannot function or adapt outside its programming rules. Studies show that AI-generated code often encounters unexpected errors or even fails, since it cannot function beyond its programming. (MIT,2025) Since AI only really regurgitates information, when the problem is something unexpected and new, the AI may not know what to do next. Even if this happens, my experience and judgment can help me troubleshoot or solve issues in which AI cannot. Human programmers are still needed to troubleshoot, fix, or guide code when issues come up because, as of now, AI cannot independently self-diagnose or resolve problems itself. (MIT,2025) Since it cannot do these things on its own, humans are needed to prevent delays and ensure the project stays on track. Coding projects will always have bugs and errors regardless of the complexity; therefore, my ability to adapt and use my skills is still needed. 62% of AI-generated code solutions contain design flaws or known security vulnerabilities, even when developers used the latest foundational AI models.(McCarthy,2025)That 62% is a high number and that means that humans must continue to be needed to monitor or repair for the success of the project. This shows that human adaptability will continue and always will be a part of software development.

My skills allow me to adapt to new roles since my job might change instead of disappear. AI will shift coding jobs in a new direction rather than eliminating them, which creates new jobs that require slightly different skills. “According to Morgan Stanley Research, the rise of AI-powered coding tools is not eliminating jobs—it’s creating new opportunities for developers and software companies alike.”(Morgan Stanley, 2025) This shows that programmers will evolve into new roles that still offer employment or careers instead of eliminating them. My creativity and deep thinking let me learn new tools, how to supervise AI, design systems, and fix its mistakes. As AI takes over repetitive tasks, programmers are starting to shift into new roles like system design, oversight, and fixing errors. (Morgan Stanley, 2025) This shows that advanced thinking, which humans can do better, will not be replaced by AI since it cannot be done. Programmers who are able to be dynamic and adapt to the new roles will be able to maintain their jobs, which shows that AI won’t erase it but instead shift it. “Contrary to current market concerns that AI will replace human developers, we believe it will enhance productivity and lead to more hiring,” (Morgan Stanley, 2025) The ability to adapt to different roles will help protect jobs and give more opportunities for the future. Since I’m more than willing to adapt to new roles and learn new skills, I will be okay with the growth of AI systems instead of fearing it. Because of this flexibility I will be able to stay relevant no matter what happens in the future of AI.

In conclusion AI might be changing the world of coding forever, but that doesn’t mean that the qualities that humans have will be replaced which makes them remain an essential part. While AI is great at doing repetitive or routine tasks, it lacks the ability to create new ideas, understand complicated issues, or make accurate, thoughtful decisions that real world projects need. Coding will still rely on creativity, judgement, critical thinking, and problem solving skills that only programmers including me can provide. As AI continues to become more advanced

and shift how programming is done, people will still be needed to provide all the right insight. The future will only push programmers to adapt to different roles that require decision making or thinking skills. Instead of removing humans, Ai will change how coding works and therefore change how we work as well. It will create new jobs that focus more on guidance, design, oversight, and judgement which will only shift programming not limit it. Because of all these factors future programmers like me are still going to have to adapt but will still play a necessary role in development and AI control.
